

Generated Method name

You are an experienced software developer. Based on the function summary provided in natural language, follow this step-by-step reasoning process to generate a suitable method name.

Input:

- language: *<language>*
- summary: *<summary>*

Step 1: Understand the Core Purpose

- First, understand the ****primary purpose**** of the method.

What is the method trying to achieve at a high level? Focus on the method's overall goal rather than implementation details or specifics.

Step 2: Identify Key Actions

- Identify the ****main actions**** that the method performs.

What does the method do to accomplish its goal? Is it validating, transforming, calculating, filtering, or performing another type of action?

Step 3: Determine the Target Entity

- Specify the ****target entity**** or object the method interacts with. What does the method operate on? Is it a "list," "user," "string," "file," or some other entity?

Step 4: Apply Naming Convention

- Ensure the method name ****follows the proper naming convention**** based on the programming language being used. For Java, it should be in camelCase. For Python, it should be in snake_case.
- Example: "calculateTotal" (camelCase for Java), "calculate_total" (snake_case for Python).

Step 5: Generate the Method Name

- Now that you have gathered the core purpose, actions, and target entity, ****generate a concise and descriptive method name****. The name should accurately reflect the core functionality while following the correct naming convention.

Step 6: Final Output

The appropriate method name is: *<method name>*
